

ABSTRACT OF THE DISCLOSURE

Multi-extension functionality is provided to a group of two or more mobile terminals in a wireless communication network by the provision of a common number associated with the group. The common number and identification of all mobile terminals in the group are stored in a subscriber database. When a call directed to the common number is received, the caller may be prompted to select an option for contacting group members, such as calling a specific group member, the first to answer, or all group members. Mobile terminals in the group are paged accordingly via their individual telephone numbers, and the appropriate call connections established. The call placement action may be predetermined, selected by the caller, or dependent on extrinsic data. Calls placed by group members may have the common number reported in caller-ID in lieu of their individual telephone numbers.
